OXIDES OF NITROGEN EMISSIONS FROM THE TESTING OF
TF41-A-2B ENGINES AT NAS LEMOORE, CALIFORNIA

AESO Report No. 1-88
November 1987

EXECUTIVE SUMMARY

Oxides of nitrogen (NO_x) are an air pollutant from the testing of gas turbine engines. Out-of-airframe engine testing is regulated by air pollution control agencies which require NO_x emissions data on applications for permits to construct and operate engine test facilities. Aside from continuous emissions monitoring, current methods of determining NO_x emissions from test cells depend on the availability of accurate records of engine operational data. This degree of record keeping is excessive given the difficult conditions under which engine testing is normally conducted. To avoid excessive record keeping, the Aircraft Environmental Support Office recommends a simple procedure for the determination of NO_x emissions. Its use depends only on accurate records of fuel usage for each engine test run.

The procedure involves the use of a correlation coefficient which relates the weight (pounds) of NO_x emissions to the weight (pounds) of fuel consumed during engine testing. The coefficient is characteristic of a given engine type, demonstrating little variation among individual engines. This report establishes a correlation coefficient for the TF41-A-2B engine based on actual emissions data and the run sheets from 27 engine tests conducted in test cells at NAS Lemoore, California. The correlation coefficient, equal to 0.01515 pounds of NO_x formed per pound of fuel consumed, determined NO_x emissions to within 1% of actual values. An analysis of the statistical validity of the coefficient supports its use as a reliable procedure.

OXIDES OF NITROGEN EMISSIONS FROM THE TESTING OF
TF41-A-2B ENGINES AT NAS LEMOORE, CALIFORNIA

AESO Report No. 1-88
November 1987

1. INTRODUCTION

Oxides of nitrogen (NO_x), a combination primarily of nitrogen oxide and nitrogen dioxide, are an air pollutant from the testing of gas turbine engines. Engine test cells therefore constitute a stationary source of NO_x emissions. Unless otherwise exempt, newly constructed or modified test cells must comply with federal New Source Performance Standards. (1) These standards were designed to regulate operations with continuous emissions, such as power plants and refineries. However, engine test cells are inactive for many days of the year, and are therefore not continuous emission sources.

The amount of NO_x formed during engine testing is part of the information required on applications to regulatory agencies for authority to construct and permission to operate test facilities. To assist NAS Lemoore in complying with local emissions regulations, the Aircraft Environmental Support Office (AESO) developed a procedure for determining NO_x emissions. The procedure establishes a correlation coefficient which relates the weight of NO_x emissions produced to the weight of fuel consumed during an engine test run. The correlation coefficient can be used to determine NO_x emissions over a specified compliance period, based only on values of fuel usage per engine test run.

This report establishes a correlation coefficient for the TF41-A-2B engine based on a sample of 27 engine tests conducted in test cells at NAS Lemoore, California. An analysis of the statistical validity of the coefficient is presented to support its use. AESO used a similar approach in an earlier report to establish a correlation coefficient for the F404-GE-400 engine. (2) The general approach is described in the next section.

2. EMISSION INDEXES AND ENGINE OPERATIONAL DATA

2.1 EMISSION INDEXES

An emission index relates the amount of a pollutant in the engine exhaust to the amount of fuel used. It is commonly expressed as pounds of exhaust constituent per 1,000 pounds of fuel consumed. This report considers only a single pollutant, oxides of nitrogen. The emission index for NO_x is calculated from measured concentrations of carbon monoxide, carbon dioxide, oxides of nitrogen and hydrocarbons in the engine exhaust.

The emission index for NO_x varies with engine power setting, being lowest at idle and highest at full power (military mode). In order to calculate the amount of NO_x formed at each power setting, an appropriate value of the emission index must be known. To establish these values, AESO evaluated the measured gaseous emissions data from 7 TF41-A-2B engine test reports. (3) Each test report provides values of the emission index for 6 power settings between idle and full power. Figure 1 shows a semi-logarithmic plot of emission index versus thrust for the reported gaseous emissions data. A simple curve fitting program was used to generate an exponential curve fit defined by the equation

$$y = ae^{bx} \quad (1)$$

where a and b are constants ($a = 2.02$ and $b = 1.76 \times 10^{-4}$) determined by the program, y is the emission index and x is the thrust in pounds. The coefficient of determination, r^2 , for the resulting fit is 0.93301.

Only data corresponding to thrust values in the range from 4,000 to 15,000 pounds were used to generate the curve fit. The TF41-A-2B engine is rated at 15,000 pounds of thrust. Therefore regular engine testing above this limit was not conducted. As seen from Figure 1, the relationship between emission index and thrust is not exponential for thrust values between idle and 4,000 pounds. For this reason an average value of 1.6 was calculated as the emission index for idle. Equation (1) is then used to calculate the emission index for thrust settings within the specified range, for any TF41-A-2B engine.

2.2 ENGINE OPERATIONAL DATA

This section of the report describes the organization of the data in Tables 1 - 27. The TF41-A-2B engine run sheets on which these tables are based are included in Appendix A. Tables 1 - 9 contain engine data from test cells at NAS Lemoore. The tests were conducted from May through July of 1987. Tables 10 - 27 contain engine data from earlier tests also conducted in test cells at NAS Lemoore - testing occurred from August through November of 1985. The engine run sheets, on which these tables are based sometimes lacked thrust and fuel consumption values at idle and military operation. Estimated values are provided for these parameters. At idle the TF41-A-2B demonstrates an average thrust of 640 pounds and an average fuel flow rate of 1,050 pounds per hour. At military the average thrust is about 12,800 pounds, and the average fuel flow rate is 8,040 pounds per hour.

The first 4 columns of each table contain the engine operational parameters. These 4 parameters are: rpm, thrust, fuel flow, and time of operation at a specified power setting. For the purposes of this report, rpm is used only as a means of data identification. It is not used computationally. The rpm provides an indication of the relative power setting for each row of data in the tables, ranging from idle (7,000 rpm) to full power (12,800 rpm). Equation (1) and the remaining 3 parameters are then used to determine the entries in the next 3 columns; "Fuel use", "EI" and "Pounds of NO_x". Section 2.3 describes the calculations and summarizes the results.

2.3 CALCULATIONS AND SUMMARY OF RESULTS

2.3.1 CALCULATIONS

Tables 1 - 27 present TF41-A-2B engine test data and the resulting NO_x emissions. The amount of NO_x formed at each power setting is determined as follows. Each row of data in the table, identified by an rpm, corresponds to a power setting. By using the fixed emission index at idle (1.60) and equation (1) for all other power settings, this report calculates an emission index for each recorded thrust value. The fuel usage (pounds) is calculated by multiplying the fuel flow by the time, which must first be converted into hours. A division of the fuel usage by 1,000 (the emission index is for pounds per 1,000 pounds of fuel used) and multiplication by the emission index then gives the "pounds of NO_x " formed at that power setting. A summation of the NO_x emissions from all the power settings in a table gives the total NO_x emissions for that engine test.

Tables 1 - 27 conclude by calculating the total fuel consumption and the total NO_x emissions for the test. A division of the total pounds of NO_x by the total pounds of fuel used gives the pounds of NO_x formed per pound of fuel. This value is the correlation coefficient discussed in the introduction. Note that this parameter has a function similar to that of the emission index, although it is expressed somewhat differently.

2.3.2 COMPUTER PROGRAM

A FORTRAN program was used to perform the calculations and to generate the tables. The program documentation and coding appear in Appendix B. A catalog of environmental calculations, also available from AESO, describes how to use a small programmable calculator to establish emission indexes and to estimate the amounts of NO_x formed during engine testing. (4)

2.3.3 SUMMARY OF RESULTS

The results of Tables 1 - 27 are summarized in the first 4 columns of Table S1. Column 4 contains the correlation coefficient for the individual engine tests. The mean correlation coefficient for the entire sample is 0.01515 pounds of NO_x formed per pound of fuel consumed. The standard deviation for the sample, equal to 0.00137, quantifies the variability of the individual test results.

Column 5 of the same table contains the calculated amounts of NO_x emissions, which are derived from the mean correlation coefficient. The calculated amounts compare closely with the amounts determined from the emission indexes. Column 6 reports the percentage differences for the individual engine tests, which vary from -21.37% to +22.68%. However, the total calculated amount of NO_x emissions for the sample agrees to within less than 1% of the actual amount. Although individual engine tests may demonstrate significant percentage differences, use of the correlation coefficient to determine NO_x emissions produces reliable results for larger samples.

3. STATISTICAL ANALYSIS

The sample used to establish the correlation coefficient in the previous section is only a limited subset of all TF41-A-2B engine tests. However, it is desirable to infer from this sample about characteristics pertaining to the entire population. Statistical inference from a sample is useful only if that sample has been randomly chosen, and is representative of the population from which it was obtained. The 27 TF41-A-2B engine tests evaluated in this report were chosen because they were conducted during 2 arbitrarily established calendar intervals, one in 1985 and the other in 1987. The selection was therefore random, and the sample should be considered representative of the population.

To demonstrate that the use of the correlation coefficient is a statistically valid means of determining NO_x emissions, it is necessary to show that any apparent discrepancies between the actual and calculated amounts of NO_x are due only to random sampling error, and not to failure of the procedure. The 2 parameters of interest, actual and calculated NO_x emissions, are not independent of each other; they are paired through the procedure used to establish the correlation coefficient. The applicable statistical method is the t-test for paired observations, which is described in many standard texts on probability and statistics. (5) An extension of the t-test for paired observations is recognized by the Environmental Protection Agency as a method for certifying NO_x monitoring equipment. (6)

Table S2 presents the results of the statistical analysis, and provides a brief outline of the equations used in the calculation procedure. The first 3 columns of the table duplicate information from Table S1, while the next 2 columns report the intermediate results. The important statistical parameters are then summarized at the bottom of the table.

The values in column 4 are the differences between the actual and the calculated amounts of NO_x for each engine test. The estimated standard deviation, a value which describes the variability among these differences, is used to derive a standard error for the mean of differences. The standard error quantifies how well the mean difference for the sample estimates the mean difference for the population, which is usually zero. From the estimated standard error, and an appropriate t-value, confidence limits for the sample mean difference can be determined.

95% confidence limits, based on a two-tailed test, are appropriate. The expected confidence interval for the sample mean difference is then 1.66 ± 5.40 . The absolute magnitude of this confidence interval determines the relative accuracy, which describes how closely the proposed procedure compares to the reference method (calculation of NO_x emissions based on the emission indexes). The relative accuracy determined from this statistical analysis is 3.79%. This means that one can be 95% confident that the correlation coefficient will determine NO_x emissions which are within 3.79% of emissions calculated by using the emission indexes.

4. CONCLUSIONS

The rate at which the testing of TF41-A-2B engines produces NO_x emissions can be expressed as a correlation coefficient. This coefficient can then be used to determine the amount of NO_x emissions formed during any engine test, based only on records of fuel consumption. The correlation coefficient for the TF41-A-2B engine is 0.01515 pounds of NO_x formed per pound of fuel consumed. An analysis of the statistical validity of the coefficient supports its use.

12779	12880	8633	7	1007.2	19.49	19.63

Emission index (EI) for NOx is expressed as pounds of NO₂ per 1000 pounds of fuel.

- (a) An rpm of 7000 indicates that the engine is operating at idle. The corresponding thrust and fuel flow are estimated.
- (b) An rpm of 12800 indicates that the engine is operating at military. The corresponding thrust and fuel flow are estimated.

TABLE 3 (continued)

RPM	THRUST (lb)	FUEL FLOW (lb/hr)	TIME (MIN)	FUEL USE (lb)	EI	POUNDS NOX
12016	8680	5545	6	554.5	9.31	5.16
12248	10160	6553	8	873.7	12.08	10.55

Emission index (EI) for NOx is expressed as pounds of NO₂ per 1000 pounds of fuel.

- (a) An rpm of 7000 indicates that the engine is operating at idle. The corresponding thrust and fuel flow are estimated.
- (b) An rpm of 12800 indicates that the engine is operating at military. The corresponding thrust and fuel flow are estimated.

Emission index (EI) for NOx is expressed as pounds of NO₂ per 1000 pounds of fuel.

- (a) An rpm of 7000 indicates that the engine is operating at idle. The corresponding thrust and fuel flow are estimated.
- (b) An rpm of 12800 indicates that the engine is operating at military. The corresponding thrust and fuel flow are estimated.

TABLE 25 (continued)

RPM	THRUST (lb)	FUEL FLOW (lb/hr)	TIME (MIN)	FUEL USE (lb)	EI	POUNDS NOX
12581	14525	9823	7	1146.0	26.04	29.84

totals	5028.20	4983.28	44.92	4914.25
means	186.23	184.57	1.66	

Estimated standard deviation = 13.64

Estimated standard error = 2.63

95% confidence limits = ± 5.40

Relative accuracy = 3.79%

(a) Difference = NOx (per test) - NOx (calc'd)

See notes i - iv.

TABLE S2. (continued)

Notes:

i. Estimated standard deviation:

$$S_d = \sqrt{\frac{\sum d^2 - (\sum d)^2/n}{n-1}}$$

ii. Estimated standard error:

$$S_{\bar{d}} = \frac{S_d}{\sqrt{n}}$$

iii. 95% confidence limits (two-tailed test):

$$CC = t_{0.95} S_{\bar{d}} \quad \text{where } t_{0.95} = 2.056 \text{ for } n = 27$$

iv. Relative accuracy:

$$RA = \frac{|\bar{d}| + |CC|}{\bar{RM}} \times 100 \quad \text{where } \bar{RM} \text{ is the average "reference method" value}$$

```

***** C-* PROGRAM TF41 *****
** C-* PURPOSE:
** THIS PROGRAM CALCULATES A CORRELATION COEFFICIENT TO ESTIMATE
** THE AMOUNT OF OXIDES OF NITROGEN PRODUCED DURING TF41 ENGINE
** TESTING. THE CORRELATION COEFFICIENT IS EXPRESSED AS AN
** "EMISSIONS TO FUEL RATIO" WHICH ESTIMATES TOTAL NOX EMISSIONS
** ON THE BASIS OF TOTAL FUEL USE ALONE.
C-* C-* PROGRAMMER:
C-* VERONICA J. HOBAN
C-* AIRCRAFT ENVIRONMENTAL SUPPORT OFFICE
C-* NORTH ISLAND, CA
C-* AUGUST 12, 1987
C-* C-* VARIABLES:
C-* IDENTIFIER TYPE DESCRIPTION
C-* KOUNT INTEGER # OF ENGINE TEST RUNS
C-* N INTEGER # OF ENGINE POWER SETTINGS PER TEST
C-* IESN INTEGER ENGINE SERIAL # (LIMITED TO 6 DIGITS)
C-* J,K,L INTEGER MONTH, DAY, YEAR OF ENGINE TEST RUN
C-* RPM REAL ENGINE POWER SETTING IN rpm
C-* THRUST REAL ENGINE THRUST IN POUNDS
C-* FUEL REAL ENGINE FUEL RATE PER POWER SETTING IN
C-* POUNDS/HOUR
C-* TIME REAL TIME AT A GIVEN POWER SETTING IN MINUTES
C-* EI REAL EMISSION INDEX EXPRESSED AS POUNDS OF
C-* OXIDES OF NITROGEN PER 1000 POUNDS OF
C-* FUEL
C-* FUELUSE REAL POUNDS OF FUEL USED PER POWER SETTING
C-* NOX REAL POUNDS OF OXIDES OF NITROGEN RELEASED
C-* PER POWER SETTING
C-* TFUEL REAL TOTAL FUEL USE IN POUNDS FOR THE ENGINE
C-* TEST RUN
C-* TNOX REAL TOTAL AMOUNT OF OXIDES OF NITROGEN
C-* RELEASED FOR THE ENGINE TEST RUN
C-* COEFF REAL CORRELATION COEFFICIENT FOR EACH ENGINE
C-* TEST RUN
C-* ACOEFF REAL AVERAGE CORRELATION COEFFICIENT FOR ALL
C-* TEST RUNS IN THE INPUT DATA FILE

C-* ADDITIONAL VARIABLES WERE USED AS TEMPORARY STORAGE
C-* C-* INPUT:
C-* THE INPUT DATA FILE IS "ENGINE.DAT", AND READING OF THE DATA
C-* IS LIST DIRECTED.
C-* THE 1st RECORD CONTAINS "KOUNT" WHICH APPEARS ONLY ONCE IN
C-* THE DATA FILE.
C-* THE NEXT N RECORDS CONTAIN "THRUST,RPM,FUEL,TIME" WHICH MUST
C-* BE EXPRESSED AS REAL VALUES (DECIMAL POINT INCLUDED).
C-* EACH SUBSEQUENT SET OF ENGINE RUN DATA IS ENTERED IN A
C-* SIMILAR MANNER.

C-* OUTPUT:
C-* THE OUTPUT DATA FILE IS THE STANDARD OUTPUT DEVICE (LINE

```

-* PRINTER "LPT1"). THE OUTPUT IS NOT STORED ON DISK.

C-* METHOD:

THE CALCULATION METHOD USED IN THIS PROGRAM IS DESCRIBED
IN AESO REPORT No. 4-85 (JULY 1985) & AESO REPORT No. 10-87
(NOVEMBER 1987).

-* RESTRICTIONS:

C-* THIS PROGRAM IS DESIGNED FOR THE TF41 ENGINE. IT MAY BE USED
C-* FOR OTHER ENGINE TYPES AFTER SOME MINOR MODIFICATION.
-* 1. REVISE HEADER FORMAT TO REPRESENT ALTERNATE ENGINE TYPE
-* 2. REVISE THE LINE $EI=a*EXP(b*THRUST)$ TO INCLUDE VALUES OF
C-* a AND b WHICH REPRESENT THE ALTERNATE ENGINE TYPE
-* 3. REVISE FINAL FORMAT STATEMENT TO REPRESENT ALTERNATE
-* ENGINE TYPE.
